

Influence of soil amendment on the relative growth rate and net assimilation rate of *Phaseolus vulgaris* and *Vigna aconitifolia*

Abstract

Background: Soil pH is one of the most influential factors that affects crop growth and productivity. This research was designed to assess the influence of soil amendment using organic manure and agricultural lime on the relative growth rate (RGR) and net assimilation rate (NAR) of *Phaseolus vulgaris* and *Vigna aconitifolia*.

Methodology: The three locations were: Akamkpa with pH 4.0, Calabar Municipality with pH 7.0 and Odukpani with pH of 9.0. The treatments were; control (0g), OM₁ (100g organic manure), OM₂ (200g organic manure), AL₁ (100g agricultural lime), AL₂ (200g agricultural lime), OM₁ + AL₁ (50g organic manure + 50g agricultural lime) and OM₂ + AL₂ (100g organic manure and 100g agricultural lime).

Results: Results obtained on the RGR of the leaf dry weight of *P. vulgaris* treated with OM₂ was the highest (0.50 gg⁻¹wk⁻¹) followed by OM₁ (0.41 gg⁻¹wk⁻¹). OM₁ + AL₁ had the highest RGR of the stem dry weight of *P. vulgaris* grown on soil from Calabar Municipality. In the RGR of the root dry weight, OM₂ had the highest mean value in both plants grown on Akamkpa soil. Results obtained at 4 weeks after planting (WAP) revealed that there was significant (P<0.05) increase in NAR of plants grown on soil from Akamkpa. The highest NAR was obtained for *V. aconitifolia* treated with OM₂ (0.0447 gg⁻¹wk⁻¹) followed by OM₂ + AL₂ (0.0057 gg⁻¹wk⁻¹) for both *V. aconitifolia* and *P. vulgaris*. *P. vulgaris* grown on Akamkpa and Odukpani soils treated with AL₂ (0.0032 gg⁻¹wk⁻¹), OM₁ + AL₁ (0.0041 gg⁻¹wk⁻¹) and OM₂ + AL₂ (0.0062 gg⁻¹wk⁻¹) had the highest NAR at 8 WAP.

Conclusion: The RGR and NAR of the two bean varieties were greatly improved following treatments with organic manure and agricultural lime.

Keywords: Relative growth rate, Net assimilation rate, dry matter and soil

Introduction

Phaseolus vulgaris (L.) and *Vigna aconitifolia* (Jacq.) are two important beans in the family Fabaceae. This is the third largest family of angiosperms after orchidaceae (orchids) and Asteraceae, and second only to Poaceae (grasses) in terms of agricultural and economic importance (Garg *et al.*, 2014). The family includes a large number of domesticated species for human and horticultural purposes (Lewis *et al.*, 2005). Beans are globally important leguminous vegetables that have been used for centuries (Brink and Belay, 2006) as food for humans and feed for animals (Amira *et al.*, 2003). Primarily, beans are rich in protein and relatively low in fiber making them a potentially valuable ingredient for all livestock species. Beans are also a major source of calories. In addition, its consumption provides mineral especially iron and zinc for which it compliments cereals. Most legumes have symbiotic nitrogen-fixing bacteria in the root nodules, hence they play a key role in nitrogen fixation in soil. *P. vulgaris* and *V. aconitifolia* are considered important sources of dietary protein for the majority of the people who cannot afford expensive animal protein thereby

46 eliminating human malnutrition. The leaves are also occasionally used as vegetable
47 and the straw as fodder (Ndakidemi *et al.*, 1998).

48 The performance of plants depends very much on the soil factors. Acidic and alkaline
49 soil have been found to affect the yield and development of legumes (Brady and Weil,
50 2008; Thakuria *et al.*, 2016). The fundamental factors associated with acidic and
51 alkaline soils include, nutrient deficiencies such as phosphorous, calcium, nitrogen,
52 and the presence of phytotoxic substances such as soluble aluminum and manganese
53 (Carren, 1991). In the soil, plants absorb nutrients mainly in soluble form. Under
54 acidic and alkaline conditions, some of these vital nutrients such as phosphorous,
55 calcium and magnesium are unavailable or are only present in minute quantities (Liu
56 *et al.*, 2010). It has been found that herbaceous plants are more sensitive to the effects
57 of acidic and alkaline soils than woody plants (Heckle *et al.*, 2005). Adverse impacts
58 of nutrients deficiency on plants include chlorosis, stunting, senescence and several
59 other symptoms (Evans *et al.*, 1997). Legumes production require large amount of
60 nutrients for their growth and development otherwise, physiological deficiencies can
61 occur (Takahashi, 1981).

62

63 Over the years, inorganic fertilizers have been used worldwide to support and
64 optimize the growth of plants. However, the use of organic fertilizers has gained more
65 global interests in the last few decades due to concerns about the impacts of inorganic
66 fertilizers in food chains, human health and the environment (Shehata *et al.*, 2011).
67 There is large increase in the use of organic fertilizers over inorganic fertilizers as
68 nutrient source on many farms (Kannan & Savannah, 2006; Joshi *et al.*, 2016, Effa *et al.*,
69 2019; Menon *et al.*, 2010; Adeoye *et al.*, 2011). Apart from improving the fertility,
70 structure and some biological properties of the soil, organic materials has the capacity
71 to reduce soil acidity and aluminum saturation. A number of possible mechanisms
72 have been suggested by several workers decades ago in their quest to elucidate how
73 this occurs (Gaur, 1991). Several liming materials such as crushed limestone
74 (CaCO_3), dolomitic lime (CaMgCO_3), slaked lime (Ca(OH)_2), quick lime (CaO) have
75 been used to reduce soil acidity (Lathwell 2012; Buri *et al.*, 2005; Kisinyo *et al.*,
76 2005; Kisinyo *et al.*, 2005; Rothwell and Dodd (2014). Studies have shown that apart
77 from reducing the acidity of the soil by counteracting the effects of excess hydrogen
78 and aluminum ions (Fageria and Baligar, 2005), liming also has several other benefits
79 including, its ability to reduce the toxicity effects of some micro elements by lowering
80 their concentrations while increasing the availability of plant nutrients such as
81 calcium, phosphorus, molybdenum and magnesium in the soil (Naidu *et al.*, 1990) and
82 reducing the solubility and leaching of heavy metals (Sauve *et al.*, 2000). The use of
83 organic manure and agricultural limes as independent treatments notwithstanding,
84 reports have shown that a combination effect of the two fertilizer sources can be more
85 effective in improving crop growth and yield components (Effa *et al.*, 2019; Reyhand
86 and Amiraslani (2006); Luqueno *et al.* (2010), Manivannan *et al.* (2009) and Joshi *et al.*
87 (2016). The present study was designed to assess the influence of organic manure
88 and agricultural lime singly and in combination on the relative growth rate and net
89 assimilation rate of *Phaseolus vulgaris* and *Vigna aconitifolia*.

90

91 **MATERIALS AND METHODS**

92 **Study location**

93 The experimental site for this study was at the Greenhouse, Department of Plant and
94 Ecological Studies, University of Calabar with an average temperature of $25 \pm 3^{\circ}$ C.
95 Calabar is located between latitudes $4^{\circ} 78'$ and $5^{\circ} 09'$ N and longitudes $8^{\circ} 15'$ and 8°

96 26' E and lies between the valleys of two rivers: The Great Qua River on the Eastern
97 side and the Calabar River on the West. The total annual rainfall for the area is
98 between 2109.5 mm and 4168.7 mm.

99

100 **Seeds collection and planting materials**

101 Seeds of *P. vulgaris* and *V. aconitifolia* were obtained from Institute of Agricultural
102 Research and Training (IAR and T) Moor Plantation in Ibadan, Nigeria. Polythene
103 bags (planting bags) were obtained from Ministry of Agriculture, Calabar.
104 Agricultural lime was obtained from Cross River Agricultural Development Project
105 while organic manure was obtained from the Department of Soil Science, Faculty of
106 Agriculture, University of Calabar, Calabar.

107

108 **Soil sampling, collection and preparation**

109 Soil samples (0-20 cm) depth were collected from three Local Government Areas of
110 Southern Cross River State. Soils with pH 4.0 were collected from three villages in
111 Akamkpa (Old Netim, Ayaebam and Awi), soils with pH 7.0 were collected from
112 Calabar Municipality in designated locations (Forestry and Wild-Life Plantation,
113 University of Calabar, Esuk Atu Community, Lemna dumpsite – Itung Effanga) and
114 soils with pH 9.0 were collected from three villages in Odukpani Local Government
115 Area (Akpan 18 Community, Akim-Akim and Okoyong-Usang Abasi) using an
116 auger. Soils from the same Local Government area with same pH were properly
117 mixed to give a composite soil sample. The map of Southern Cross River showing the
118 geographical locations of the soil samples is shown in figure 1. Soil for germination
119 and growth of plants were bulked air dried for three days, sieved through a 2 mm
120 mesh to remove debris and were taken to Soil Science Laboratory, University of
121 Calabar for the physico-chemical analysis.

122 **Experimental design and layout**

123 The experiment was conducted using a 2x3x7 factorial experimental layout in a
124 Randomized Complete Block Design (RCBD) with 3 replicates. Factor one were the
125 two plant varieties (*P. vulgaris* and *V. aconitifolia*), factor two were the three locations
126 where soil samples were collected (Akamkpa-AK, Calabar Municipality-CM and
127 Odukpani-OD) while factor three were the seven levels of treatment: control (0 g),
128 OM₁ (100 g organic manure), OM₂ (200 g organic manure), AL₁ (100 g agricultural
129 lime), AL₂ (200 g agricultural lime), OM₁ + AL₁ (50 g organic manure + 50 g
130 agricultural lime) and OM₂ +AL₂ (100 g organic manure and 100 g agricultural
131 lime).

132

133 **Planting procedure and treatment application**

134 One hundred and twenty-six experimental polybags (16 cm internal diameter)
135 perforated at the bottom were filled with 5 kg of each soil sample. These were
136 divided into three groups of 42 polybags based on the three soil samples. In each soil
137 sample, there were 21 polybags each for the two plant varieties using randomized
138 complete block design (RCBD) replicated three times. The soils were treated with
139 agricultural lime (AL) and organic manure (OM) singly and in combinations. The
140 treated soils were allowed to stay for two weeks before seed sowing. This time lapse
141 before planting was to allow for microbial activities and interaction within treatment
142 combinations. Each polybag was sown with three seeds each of *P. vulgaris* and *V.*
143 *aconitifolia* at a depth of 2 cm. Following germination, seedlings stalk were watered and
144 grown for 8 weeks.

145

146 **Determination of leaf, stem and root dry weight**

147 Seven plants were carefully uprooted from each treated soil. In order to prevent some
148 portions of the root from breaking off, the plants were placed in a container of water
149 and the soil gently washed off. The stem of each plant was cut off from the root with a
150 scissor while the leaves were picked from the stem by hand. The leaf, stem and root
151 were dried to constant weight (DW).

152

153 **Determination of relative growth rate**

154 The relative growth rate (RGR) measured the change in dry weight (dw) of different
155 samples of *P. vulgaris* and *V. aconitifolia* grown on acidic and alkaline soil treated
156 with different grams of organic manure and agricultural lime. The differences were
157 calculated between plants grown on acidic and alkaline treated soils by the method of
158 (Hoffmann and Poorter, 2002) and the fresh weight of whole plant was used in the
159 determination of RGR.

$$160 \quad \text{RGR} = \frac{(\ln W_2 - \ln W_1)}{t_2 - t_1} (\text{gg}^{-1} \text{wk}^{-1})$$

161 Where:

162 \ln = natural logarithm.

163 W_1 = initial dry mass or weight.

164 W_2 = final dry mass or weight.

165 t_1 = initial growth period.

166 t_2 = final growth period.

167 $t_1 - t_2$ = time interval during which time biomass increased from $W_1 - W_2$.

168

169

170 **Determination of net assimilation rate (NAR)**

171 NAR was calculated as the change in total plant biomass per leaf weight and time
172 (Heilmeyer *et al.*, 1986). Time was used to show the photosynthetic effectiveness
173 between *P. vulgaris* and *V. aconitifolia* grown on acidic and alkaline soils treated with
174 organic manure and agricultural lime.

$$175 \quad \text{NAR} = \left(\frac{\ln A_2 - \ln A_1}{A_2 - A_1} \right) \left(\frac{W_2 - W_1}{t_2 - t_1} \right) (\text{gg}^{-1} \text{wk}^{-1})$$

176 Where:

177 \ln = Natural logarithm.

178 A_1 = Initial leaf area.

179 A_2 = Subsequent leaf area.

180 W_1 = Initial leaf dry weight.

181 W_2 = Final leaf dry weight.

182 t_1 = Initial growth period.

183 t_2 = Final growth period.

184

185 **Statistical analysis**

186 Data obtained on the relative growth and net assimilation rates were taken as the mean
187 measurements of three replicates. Statistical analysis was performed using the
188 statistical package for social sciences (SPSS) version 20.0 under a two-way analysis
189 of variance (ANOVA). Significant means were separated using the Duncan multiple
190 range test at $p < 0.05$.

191 **Results**

192 **Effect of agricultural lime and organic manure on leaf dry weight (g/plant-1)**

193 Leaf dry weight (LDW) of *V. aconitifolia* grown in soils from Akamkpa and
194 Odukpani treated with $OM_1 + AL_1$ and OM_2 showed significant ($P < 0.05$) increase at 4
195 WAP and 8 WAP when compared to the plant grown on untreated soil (Table 1). The

196 highest LDW of *V. aconitifolia* treated OM₁+ AL₁ had the mean value of 3.47 g from
197 Akampkpa soil and 4.79 g from Odukpani soil at 4 WAP as against untreated soil
198 values of 0.57 g and 1.86 g. At 8 WAP, *V. aconitifolia* grown with OM₁+ AL₁ had
199 significant (P<0.05) increase in LDW of 6.94 g and 9.58 g in Akampkpa and Odukpani
200 soils compared to the controls (1.13 g and 3.71 g). Leaf dry weight of *P. vulgaris* and
201 *V. aconitifolia* grown on AK soil treated with AL₁ and AL₂ resulted in a decrease in
202 LDW compared to the control at 4 WAP and 8 WAP. There was no significant
203 (P>0.05) difference in LDW at 4 WAP and 8 WAP for both plants grown on CM
204 treated and untreated soils.

205 206 **Effect of agricultural lime and organic manure on stem dry weight (g/plant⁻¹)**

207 Results of mean stem dry weight (SDW) of *P. vulgaris* and *V. aconitifolia* grown on
208 acidic soil from Akampkpa, Odukpani and Calabar Municipality treated with
209 agricultural lime and organic manure are presented in Table 2. Some soil amendment
210 caused significant (P<0.05) increase and decrease in SDW of plants when compared
211 to the control. There was a significant (P<0.05) increase in mean stem dry weight of
212 *P. vulgaris* grown on soil from AK treated with OM₂ + AL₂, OM₁ and OM₁ + AL₁
213 with 1.57 g, 1.14 g and 1.02 g at 4 WAP compared to the control values of 0.37 g. *P.*
214 *vulgaris* grown on acidic soil from AK treated with OM₂ + AL₂ at 8 WAP had the
215 highest SDW with mean value of 3.14 g compared to untreated soil value of 0.74 g. *V.*
216 *aconitifolia* grown on soil from OD treated with OM₂ had the highest stem dry weight
217 value of 7.89 g compared to untreated soil value of 2.70 g at 8 WAP. There were no
218 significant (P>0.05) difference in stem dry weight of *P. vulgaris* and *V. aconitifolia*
219 grown on neutral soil from CM treated with agricultural lime and organic manure at 4
220 WAP and 8 WAP.

221 222 **Effect of agricultural lime and organic manure on root dry weight (g/plant⁻¹)**

223 Results of root dry weight (RDW) of *P. vulgaris* and *V. aconitifolia* grown on soils
224 from different locations treated with agricultural lime and organic manure at 4 WAP
225 and 8 WAP are presented in Table 3. The final root dry weight was higher than the
226 initial in both plants. *V. aconitifolia* grown on soils from Akampkpa and Odukpani
227 with treated with OM₁ + AL₁ showed significant (P<0.05) difference in RDW (0.36 g
228 and 0.79 g) compared to untreated soils (0.13 g and 0.31 g). Results showed
229 significant (P<0.05) variations in the root dry weight of both plants grown on
230 Odukpani soil. The root dry weight of *P. vulgaris* and *V. aconitifolia* grown on treated
231 and untreated soil from Calabar Municipality did not differ statistically. However,
232 both *P. vulgaris* and *V. aconitifolia* produced statistically similar root dry weight at 4
233 WAP and 8 WAP obtained from OM₂ (0.79 g) in *V. aconitifolia* during the final
234 harvest when compared with the control (Table 3).

235 236 **Effect of agricultural lime and organic manure on relative growth rate of leaf 237 dry weight (gg⁻¹wk⁻¹)**

238 The results revealed that the relative growth rate of leaf dry weight of plants grown on
239 treated soil from Akampkpa and Calabar Municipality did not differ statistically
240 (p>0.05) from the untreated. However, plants grown on soils from Odukpani under
241 treatment revealed significant (P<0.05) increase in RGR of leaf dry weight when
242 compared to the control. *P. vulgaris* grown on soil from Odukpani treated with OM₂
243 had the highest RGR of leaf dry weight (0.50 gg⁻¹wk⁻¹) followed by OM₁ (0.41 gg⁻¹
244 wk⁻¹), OM₁ + AL₁ (0.37 gg⁻¹wk⁻¹) and AL₁ (0.36 gg⁻¹wk⁻¹) compared to the
245 control value of 0.13 gg⁻¹wk⁻¹. Results have shown that *P. vulgaris* and *V.*

246 *aconitifolia* grow on Odukpani soil treated with AL and OM had the highest RGR of
247 leaf dry weight (Table 4).

248

249 **Effect of agricultural lime and organic manure on relative growth rate of stem**
250 **dry weight ($\text{gg}^{-1}\text{wk}^{-1}$)**

251 Stem dry weight of *P. vulgaris* and *V. aconitifolia* grown on soils from Akamkpa and
252 Odukpani treated with AL and OM did not differ from the control. There was
253 significant ($P<0.05$) increase in the relative growth rate of stem dry weight of *P.*
254 *vulgaris* and *V. aconitifolia* grown on soil from Calabar Municipality compared to the
255 control. *P. vulgaris* grown on CM soil treated with $\text{OM}_1 + \text{AL}_1$ had the highest RGR
256 of stem dry weight of $0.48 \text{ gg}^{-1}\text{wk}^{-1}$ followed by $\text{OM}_1 + \text{AL}_1$ ($0.36 \text{ gg}^{-1}\text{wk}^{-1}$) and
257 OM_1 ($0.23 \text{ gg}^{-1}\text{wk}^{-1}$) compared to the control ($0.11 \text{ gg}^{-1}\text{wk}^{-1}$). The relative growth
258 rate of stem dry weight of *V. aconitifolia* were for AL_2 ($0.33 \text{ gg}^{-1}\text{wk}^{-1}$) and OM_1
259 ($0.24 \text{ gg}^{-1}\text{wk}^{-1}$) to the control value of $0.15 \text{ gg}^{-1}\text{wk}^{-1}$ (Table 5).

260

261 **Effect of agricultural lime and organic manure on relative growth rate of root**
262 **dry weight ($\text{gg}^{-1}\text{wk}^{-1}$)**

263 The result of relative growth rate of root dry weight of *P. vulgaris* and *V. aconitifolia*
264 depicted a trend of variation among treatments compared to the control. Soil from
265 Akamkpa showed significant ($P<0.05$) variation in relative growth rate among the
266 different treatments. *P. vulgaris* grown on Akamkpa soil treated with OM_2 had the
267 highest relative growth rate ($0.25 \text{ gg}^{-1}\text{wk}^{-1}$). The relative growth rate of *V. aconitifolia*
268 grown on Akamkpa soil treated with OM_2 had the highest relative growth rate of root
269 dry weight ($0.38 \text{ gg}^{-1}\text{wk}^{-1}$) compared to the control ($0.15 \text{ gg}^{-1}\text{wk}^{-1}$) as shown in Table
270 6.

271

272 **Effect of agricultural lime and organic manure on net assimilation rate ($\text{gg}^{-1}\text{wk}^{-1}$)**
273

274 The results on the net assimilation rate (NAR) of *P. vulgaris* and *V. aconitifolia*
275 grown on soils from Akamkpa, Calabar Municipality and Odukpani treated with
276 organic manure and agricultural lime are presented in Table 7. Results obtained at 4
277 WAP revealed that there was significant ($P<0.05$) increase in NAR of plants grown on
278 soil from Akamkpa. The highest NAR was obtained for *V. aconitifolia* treated with
279 OM_2 ($0.0447 \text{ gg}^{-1}\text{wk}^{-1}$) followed by $\text{OM}_2 + \text{AL}_2$ ($0.0057 \text{ gg}^{-1}\text{wk}^{-1}$) for both *V.*
280 *aconitifolia* and *P. vulgaris*. There were no significant differences in NAR for both
281 plants grown on soil from Calabar Municipality at 4 WAP ($P>0.05$). At 6 WAP *V.*
282 *aconitifolia* grown on soil treated with OM_2 ($0.0621 \text{ gg}^{-1}\text{wk}^{-1}$) had the highest NAR
283 followed by $\text{OM}_2 + \text{AL}_2$ ($0.0314 \text{ gg}^{-1}\text{wk}^{-1}$) which were significantly ($P<0.05$) higher
284 than other treatments for soil from Akamkpa. At 6 WAP *P. vulgaris* grown on soil
285 from Akamkpa treated with OM_1 ($0.392 \text{ gg}^{-1}\text{wk}^{-1}$), $\text{OM}_1 + \text{AL}_1$ ($0.401 \text{ gg}^{-1}\text{wk}^{-1}$),
286 OM_2 ($0.411 \text{ gg}^{-1}\text{wk}^{-1}$) and $\text{OM}_2 + \text{AL}_2$ ($0.319 \text{ gg}^{-1}\text{wk}^{-1}$) had the highest NAR. At 8
287 WAP, NAR for both plants grown on treated soil from all the treatments from
288 Akamkpa had similar NAR which were significantly ($P<0.05$) higher than the control
289 ($P>0.05$). *Phaseolus vulgaris* grown on Akamkpa and Odukpani soils treated with
290 AL_2 ($0.0032 \text{ gg}^{-1}\text{wk}^{-1}$), $\text{OM}_1 + \text{AL}_1$ ($0.0041 \text{ gg}^{-1}\text{wk}^{-1}$) and $\text{OM}_2 + \text{AL}_2$ ($0.0062 \text{ gg}^{-1}\text{wk}^{-1}$)
291 had the highest NAR at 8 WAP (Table 7).

373 **Discussion**

374 Growth is of paramount ecological importance for plant and it is highly influenced by
375 soil nutrients. A good determination of growth rate in any plant will help in
376 strategizing measures for its improvement through adoption of reliable agronomic
377 tools. Results of this study revealed that *V. aconitifolia* grown on organic manure
378 singly and in combination produced consistently higher leaf, stem and root dry
379 weights than *P. vulgaris*. The controls had lower dry matter yield while the dry matter
380 of plants grown on soil from Calabar Municipality in all the treatments were low and
381 statistically similar. This may suggest that soil from Calabar Municipality lack the
382 necessary nutrients needed for plant growth and yield. The findings corroborates with
383 the works of Badar and Qureshi (2012) and Badar *et al.* (2015) which reported
384 increase in shoot and root dry weight of cowpea following biofertilizer application.
385 This positive growth response of *P. vulgaris* and *V. aconitifolia* following application
386 of agricultural lime and organic manure may be related to the ability of the treatments
387 to increase the soil pH resulting in availability of nutrients for optimum plant growth.

388
389 Relative growth rate is the exponential increase in the size relative to the size of plant
390 present at the start of a given time interval. It is a prominent indicator of plant
391 productivity related to environmental stress and disturbance regimes. The relative
392 growth rate of leaf dry weight was higher in *P. vulgaris* grown on Odukpani soil
393 treated with organic manure and combination of organic manure and agricultural lime.
394 The relative growth rate of stem and root dry weight also showed higher values with
395 organic manure especially with 200 g organic manure. The implication is that, organic
396 manure may have the potential to enhance the growth rate of plant singly and in
397 combination with agricultural lime. It has been earlier remarked by Shipley (2002)
398 that the variation in the net assimilation rate is the main determinant of the relative
399 growth rate. This may be the reason for the similar pattern of results obtained for net
400 assimilation rate and relative growth rate.

401
402 Net assimilation rate is defined as the increase in plant dry weight per unit leaf area
403 per unit time. It is a function of the photosynthetic effectiveness of leaves of a plant
404 and its leafiness. It is a complex physico-chemical variables associated with
405 photosynthetic and respiration rates (Komings, 1989). In the present study, the net
406 assimilation rates were consistently higher in plants treated with organic manure and
407 combination of organic manure with agricultural lime. The earlier report of Effa *et al.*
408 (2019) revealed that organic manure and a combination of organic manure and
409 agricultural lime promoted faster growth rates in *P. vulgaris* and *V. aconitifolia*. It is
410 therefore possible that plants with faster growth rate may likely have higher net
411 assimilation rate as seen in the present study. This result is in line with an early
412 finding by Li *et al.* (2016), plants with faster-growth had high net assimilation rates
413 and plants with high assimilation rates always grew faster.

414
415 **Conclusion**

416 Explicitly, the results revealed that organic manure is more influential in contributing
417 to the relative growth of *P. vulgaris* and *V. aconitifolia*. Interestingly, a combined
418 effect of the two manures promoted higher growth rates and net assimilation rates
419 than single effect.
