COMMERCIAL MICROALGAE CULTURE USING AGRICULTURAL FERTILIZER AS GROWTH MEDIA

Comment [P1]: Scrub-out

Abstract

Algal biomass production using relatively and locally available NPK formulated media has been identified as a key factor in commercial algal biomass production. The suitability of agricultural fertilizer as a growth medium for commercial algae cultivation was assessed using NPK 15:15:15, NPK 20:20:20 and composite medium of NPK 15:15:15+ BG11, while BG11 was used as a control medium. Microalgae *Chlorella* sp. was cultivated in these NPK formulated media at ambient temperature under solar irradiation for a period of 15 days. The cell biomass was determined by the optical density at 660nm, cell dry weight and total chlorophyll content was also determined. The maximum value for cell biomass of 0.493 mg/L, total chlorophyll content of 0.356mg/L and cell dry weight of 0.0185mg/L achieved in the composite medium was closer to the values of 0.531 mg/L, 0.389mg/L and 0.2121mg/L for cell biomass concentration, total chlorophyll content and dry cell weight for BG11 medium. Although NPK 15:15:15 and NPK 20:20:20 media achieved lower values for cell biomass, total chlorophyll, and cell dry weight, there is no significant statistical difference between the media. This study suggests that agricultural fertilizer can be a relatively cost-effective and locally available substitute for commercial algae biomass production.

Introduction

The growing world population has resulted in a demand for alternative and renewable energy that can replace fossil fuel with minimal environmental consequences. The potentials of microalgae to yield more oil per hectare per year has drawn the attention of researchers and investors as a viable source of renewable energy. Microalgae are a group of eukaryotic unicellular photosynthetic organism that thrives in diverse aquatic habitat including soil environment. They can be unicellular flagellate or non-flagellate, colonial flagellate or colonial non-flagellate ([1]; with size ranges of 1µm-50mm depending on the species ([2] [3]. There are over 200,000 species of microalgae with less than 30,000 species being presently researched and not yet fully utilized [4]. The research in algae culture started in early 1950 by Oswald et al. who studied the cultivation of algae in sewage oxidation pond for wastewater treatment and biomass production [5]. Algae culture has passed through successive developmental phases in the past decades, attracting the attention of researchers and investors in exploring the untapped resources in algae for biologically active compounds and biofuel production. Microalgae and its bioactive compounds have found usefulness in industries such as aquaculture [6], [7], energy [8], [4], biochemical [9], wastewater [10], [11] health and pharmaceutical [12] [13]

Microalgae are fast-growing photosynthetic organisms capable of producing carbon hydrates, proteins, and lipids. They thrive in various aquatic habitats and on the surface of most soils [14],

41 utilize carbon dioxide and light energy to produce biomass and oxygen [15]). Various techniques
42 of algal culture include; photo-autotrophic, heterotrophic and mixotrophic. Algae can utilize
43 solar energy or artificial lightning as an energy source and can be cultivated in open-pond or
44 photo bioreactor system, in batch or continuous culture system. Algal growth can be affected by
45 the availability of nutrient, temperature, pH, light intensity and inoculum size. Progressively
46 microalgae pass various phases of growth depending on the concentration of nutrients in the
47 medium. The major components of algae nutrient medium are nitrogen (mainly in form of
48 nitrate, nitrite, urea or Ammonia); required as an essential component of protein, phosphorus; an
49 essential component of nucleic acid, carbon; requires for energy, vitamins, trace elements. The
50 utilization of these nutrients for biomass production has initiated the use of algae for wastewater
51 remediation and nutrients recovery. A study by [16] also reported 97% NH₄ and 96% TP
52 removal efficiency by *Chlorella vulgaris* cultivated in artificial wastewater in column aerated
53 Photobioreactors under batch and semi-continuous cultivation. Similarly, [17] reported 99.7%
54 ammonia nitrogen and 75% total phosphorus removal in piggery wastewater growing algae
55 *Chodatella* sp. Microalgae can be cultured in both synthetic and locally formulated nitrate-rich
56 medium. Some locally available media for large scale algal culture includes animal waste [18]
57 agricultural fertilizer [19] [20], [21]), sewage and industrial wastewater [22], [23] [24], [25]
58 Formulation of culture medium with locally available materials can reduce cost, preparation and
59 the complexity of synthetic medium, and subsequently the cost of biomass produced. The cost of
60 algae biomass production has been a challenge in industrial utilization and production of algae
61 value-added products and commodities.

64

65 MATERIAL and METHODS

Comment [P21]: Engage uppercase

66 Algal strain isolation and culturing

67 Pond water sample containing microalgae was collected from (ARAC) African Regional
68 Aquaculture Centre, Aluu, Rivers State and University of Port Harcourt Fish pond. Agar plating
69 techniques were used to isolate algal strains from the raw Pond water. The algal strains were
70 isolated by modifying the method of [26]. The isolated strains were sub-cultured in BG11
71 medium in natural illumination and subsequently sub culturing every seven days to maintain
72 fresh algal culture. The isolates were purified by repeated streaking on solid media and identified
73 to the genus level using standard laboratory procedures and reference materials.

Comment [P22]: Engage p

74 Culturing Parameters

75 Temperature and Light

Comment [P23]: Scrub out

76 The temperature of the medium was measured daily with (Mercury thermometer) to ensure the
77 optimum temperature for algae growth is maintained. The culture was allowed the experience
78 natural illumination from the outdoor sunlight, the daily illuminance was measured with the Lux

79 meter (Lx 9621) and the value recorded. The culture was placed below a shade to prevent photo-
80 inhibition and overheat by direct sunlight.

81 **Carbon Supply and pH Monitoring**

82 The pH of the culturing medium was adjusted within the range of 8.2-8.5; which is the optimal
83 pH for algal growth. This is measured with the portable pH meter (PHEP, pocket-size pH meter,
84 Hanna Instruments). The pH of the media was measured every 3 days. Sodium bicarbonate was
85 used as a carbon source for algae growth at the dose of 4g per litre in NPK 20:20:20 and NPK
86 15:15:15 medium.

87 **Aeration**

88 Aeration of the culture was done to prevent sedimentation and to ensure all algae cells are
89 exposed to adequate nutrient and sunlight. Aeration was achieved by constantly bubbling of air
90 from the aquarium pump, (Resun air pump, AC99041) at the rate of 9L/min and pressure of
91 0.014mpa.

92 **Nutrient**

93 The media used in the experiment are factory grade agricultural fertilizer NPK 15:15:15; (Table
94 1.3) and NPK 20:20:20 Table 1.2) purchased from the local market and the BG-II medium
95 (Table 1.1) prepared with of analytical grade chemicals, and The BG11, NPK 15:15:15 and NPK
96 20:20:20 were all prepared by accurately weighing 0.5g/L of each of the salts, and dissolved in
97 distilled water. The reactors were all autoclaved at 121°C, 15psi for 15min, while media were
98 sterilized by membrane filtration with Millipore membrane filter size of 0.45µm and 25mm
99 diameter.

130 **Analytical Procedures**

131 **Algae Biomass Concentration.**

132 Optical density was used to measure biomass concentration in the culture. The amount of light
133 absorbed by the suspended algal cell is assumed to be directly related to biomass concentration
134 [27]. Optical density was determined using a spectrophotometer at 600nm wavelength with 5 ml
135 of the growing culture. A blank absorbance was prepared by filling the cuvette with 5ml of
136 distilled water to calibrate the spectrophotometer (Spectronic 20, Genesys Thermos, USA) at
137 600nm wavelength. The cuvette containing 5ml of algae was placed in the spectrophotometer
138 and the corresponding absorbance value was recorded for each sample.

173 **RESULTS AND DISCUSSION**

174 **Cell Biomass Concentration**

175 In this study, NPK 15:15:15 and NPK 20:20:20 agricultural fertilizer was used as a nutrient
176 media for algae cultivation. The composite medium (NPK 15:15: 15 + BG 11) was formulated
177 with BG11 serving as a control medium. The *Chlorella* sp was cultured photo-autotrophically for
178 15 days in ambient temperature under solar irradiation. The Algal growth phases of induction,
179 exponential, stationary and decline phase were achieved in all the media at different incubation
180 time. A maximum biomass concentration of 0.494mg/L was obtained in the composite medium,
181 with the highest cell biomass achieved on culture day 9 as shown in figure 1.0. The maximum
182 cell biomass produced in the medium containing NPK15:15:15 + BG11 could be attributed to
183 having advantages of both NPK and Synthetic elements in the medium. The NPK 20:20:20
184 medium has the rapid growth phase with the stationary phase achieved on culture day 7 with the
185 cell biomass concentration of 0.245mg/L. This rapid growth observed in the early culture day
186 may be attributed to the varied nitrogen composition of NPK 20:20:20 which includes 10% of
187 Urea, 4% of ammonia and 6% of nitrate. Algae preference for ammonia nitrogen compares to the
188 nitrate form of nitrogen ([29]) due to less energy and time required for the nitrate uptake may be
189 responsible for the rapid early growth in NPK 20:20:20 relative to other experimented media.

191

192 **Figure 1.0. The growth curve of *Chlorella* sp in various NPK media.**

193 The medium with NPK 15:15:15 has lower growth during the exponential and linear phase, but
 194 achieved maximum growth of 0.284mg/L on culture day 9 higher than NPK 20:20:20. Although
 195 BG11 is considered a superior nutrient medium for algae growth, the agricultural fertilizer media
 196 provided required support needed for algal biomass production as shown in figure 1.0. While the
 197 composite medium achieved cell biomass concentration and longer stationary phase closer to the
 198 BG11; a known growth medium, the analysis of variance of the cell biomass concentration and
 199 the incubation time of the experiment showed no significant difference among the media. This
 200 result agrees with [29] who observed that NPK fertilizer and macrophyte can supply adequate
 201 nutrients and may replace synthetic medium for large scale algae cultivation. Similarly, the study
 202 by [30] suggested that agricultural fertilizer can provide required nutritional support for algae
 203 growth though the Bristol medium has relatively higher cell biomass concentration when
 204 compared with fertilizer medium.

Comment [P54]: Scrub out

205 **Effect of the NPK Medium on the Total Chlorophyll**

206 The result of the Chlorophyll analyses showed the BG11 and NPK15:15:15+BG 11 achieved the
 207 highest total chlorophyll content 0.383mg/L and 0. 351mg/L at the stationary phase of the algae
 208 growth respectively shown in figure 2.0. Both NPK 20:20:20 and NPK 15:15:15 medium had a
 209 short stationary phase with total chlorophyll content of 0.238mg/L and 0.268mg/L respectively
 210 as shown in figure 2.0. Since high chlorophyll content is related to the high nitrogen content of
 211 the culture medium, the high chlorophyll observed during the lag phase of NPK 20:20:20 which
 212 occurred between day 1-day 5, maybe as a result of ammonium presence in the medium, reduced

Comment [P55]: Revise long compound sentence

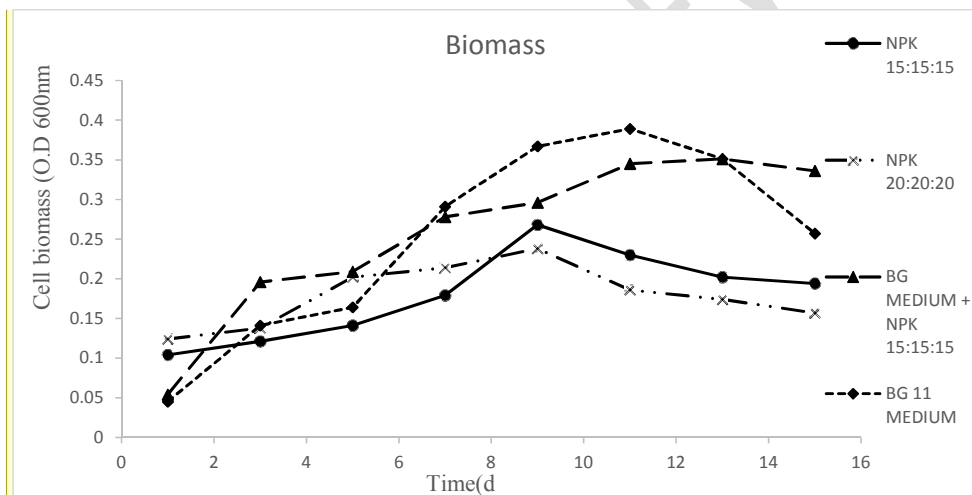

Comment [P56]: Engage c (lower case)

Comment [P57]: Engage respectively

Comment [P58]: Scrub out

213 form of nitrogen which is absent in others. Ammonium is known to be generally preferred by
 214 algae in place of other forms of nitrogen as it can be directly converted to an amino acid in the
 215 cells without further reduction [31]. However, photosynthesis inhibition occurred in NPK
 216 20:20:20 when excess ammonium was transported to the cell leading to the impediment of ATP
 217 formation in the chloroplast, thus reducing the total Chlorophyll content of the algae. This agrees
 218 with [32], who observed a 50% reduction in photosynthesis activity of *Scenedemus obliquus*
 219 cultured in high rate algal pond at 0.76nm free ammonia. On the other hand, all the media exhibit
 220 a significant reduction in chlorophyll content with nutrient depletion from culture day 9 for both
 221 NPK 15:15:15 and NPK 20:20:20, while the chlorophyll decline for BG11 and NPK+BG11
 222 occurred on culture day 11. In nitrogen depleting conditions, the chlorophyll serves as a nitrogen
 223 source that supports algal cell division and reproduction, while total depletion of nitrogen leads
 224 to the non-photosynthetic activity due to inability of the chlorophyll to facilitate the metabolic
 225 change as a result of failure to capture light and CO₂ required for the photosynthesis [33]. Thus,
 226 there is a linear relationship between biomass production and total chlorophyll content in algae.

227

239 medium of NPK15:15:15 & BG11 formulated media under photoautotrophic condition. Figure
 240 3.0 shows the biomass concentration measured as dry cell weight, the transition from the lag,
 241 exponential, linear phase, stationary and death phase for all the media. The highest cell dry
 242 weight of 0.0185mg/L was observed in the composite media of NPK and BG11 medium, figure
 243 3.0, with the stationary phase lasting from culture day 9 to 13. The lowest cell dry weight of
 244 0.0122mg/L was observed in NPK 20:20:20 medium at the stationary phase lasting from culture
 245 day 9 through day 13. Studies have revealed that various nitrogen sources have different effects
 246 on algae growth. The lower cell dry weight observed in NPK 20:20:20 medium when compared
 247 with NPK 15:15:15 medium could be due to high urea and ammonium nitrogen present in NPK
 248 20:20:20 (Table 1.1), although same quantity of NPK (0.5mg/L) was used to formulate the media.
 249 This agrees with [34] who observed a decline in the growth of *Chlorella Pyrenoidosa* due to
 250 ammonium toxicity caused by the high concentration of urea in the media. Additionally, [35] and
 251 [36] also reported inhibition of algal cell growth as a result of a high concentration of nitrogen in
 252 the media.

Comment [P62]: Revise; the information is previously mentioned under materials and methods.

Comment [P63]: Scrub out

256

257 **Figure 3.0. Cell Dry Weight of *Chlorella* sp in various NPK media**

Comment [P64]: Check formatting; e.g. Cell dry weight

258

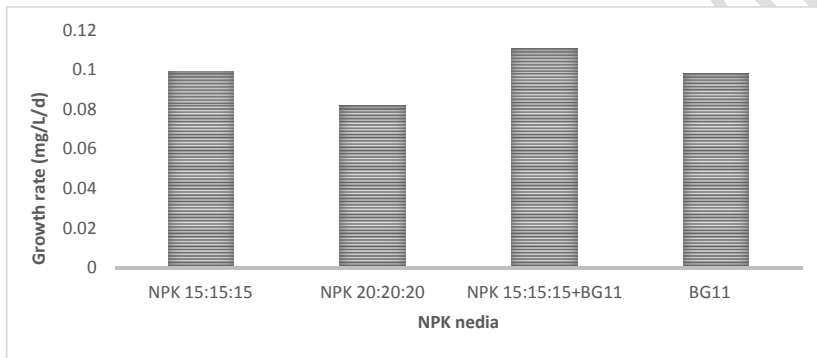

259

260

261

262 The increase in cell dry weight was observed in all the media from culture day 5 through day 11,
 263 which is considered an exponential phase of the algae growth. The dry cell biomass obtained at

264 stationary phase from both NPK of 0.0176mg/l and composite media of 0.0185mg/L were close
 265 to the value of 0.0212mg/L obtained from the BG11, which is a synthetic medium. Although the
 266 BG11 medium has been modified over the years with all the essential elements formulated for
 267 optimal growth, this experiment has shown that little modification of the NPK medium will
 268 provide a relative low cost and better nutrient medium for commercial algae biomass production
 269 [29] [21]. The growth rate and the generation time were also calculated for each of the medium
 270 shown in figure 4.0 and 5.0 respectively. The maximum value of 0.111mg/L/d for growth rate
 271 and minimum generation time of 6.24d was achieved in the composite medium of NPK and
 272 BG11 compared to other media, including the BG11 medium. The minimum value of
 273 0.082mg/L/d for growth rate and the maximum generation time of 8.45d was also observed for
 274 the NPK 20:20:20, this shows that concentration of nitrogen plays important role in the growth
 275 and algal biomass production.

285

286 Conclusion

287 The result from this study has suggested agricultural fertilizer can be a low cost and efficient
288 substitute for the synthetic growth medium for commercial algae biomass. Although a variety of
289 agricultural fertilizers can be used to formulate growth medium, emphasis should be on the NPK
290 with a lower percentage of nitrogen concentration. More so, media modification with essential
291 elements and experimenting with various concentrations of NPK will achieve optimal nutrient
292 media formulated with locally available and cost-effective growth medium for commercial algae
293 biomass production.
