

Treatment of Port Harcourt refinery effluent by a bacterial consortium immobilized on agro-based bio carriers

Abstract

Discharge of poorly treated refinery wastewater has always been a major environmental challenge. Bacterial immobilization is key to the maintenance of biomass on a contaminated site. In this study, a mixed culture of three bacterial isolates from oil-polluted water: *Pseudomonas aeruginosa* (MN294989), *Bacillus tequilensis* (MN294990) and *Micrococcus* sp. immobilized on Groundnut Shell (GS), Melon Husk (MH) and Sugarcane Bagasse (SB) were employed in the bioremediation of Port Harcourt refinery wastewater. Surface area and pore size distribution of the agro-based bio carriers were suitable for bacteria adhesion. The bacterial isolates were screened for phenol, naphthalene and hydrocarbon utilization. Scanning Electron Microscopy (SEM) was used to ascertain the immobilization of the consortium on the agro-base carriers. A 15-days laboratory-scale treatment of refinery raw wastewater was compared in the immobilised and immobilized consortium. The agro-based residue immobilized consortium enhanced the reduction in BOD₅, COD, oil and grease, phenol by 7%, 9%, 30% and 5% respectively compared to the free form of the consortium. This study underscores the role of immobilization in maintaining high bacterial biomass on contaminated site and possible improvement in bioremediation of refinery wastewater.

Keywords: immobilized consortium, bioremediation, refinery raw wastewater, bio carriers, phenol utilization

Introduction

Nigeria has four operational crude oil refineries with an estimated refining capacity of 445 000 barrels per day (Kadafa, 2012). The Federal Environmental Protection Agency (FEPA) and the Department of Petroleum Resources (DPR) are responsible for setting the minimum standards for industrial effluent discharge. Recent reports indicate that effluents discharged from refinery industries do not meet minimum set standards (Osin, Yu, & Lin, 2017; Yu & Han, 2017). In a review of the current refinery effluent treatment practices of refineries in the Niger Delta region. Osin et al. (2017) reported that receiving water bodies in the Niger Delta region of Nigeria contains most of the examined pollution parameters in concentrations above the set regulatory limits.

Pollutants in refinery effluents pose serious environmental hazards. Due to the ineffectiveness of purification systems, wastewaters may become hazardous leading to the accumulation of toxic products in receiving water bodies (Deka, Devi, & G.Bhattacharyya, 2013). The composition of these effluents

36 depends on the type of oil being processed, the plant configuration and operational procedures (Hasan,
37 Mohd, Wan, & Aziz, 2010; Ishak, Malakahmad, & Isa, 2012). Ishak et al., (2012) reported that the major
38 constituents of refinery wastewater, in general, are dissolved and dispersed oil (a mixture of hydrocarbons
39 – benzene, toluene, ethylbenzene, xylenes, polyaromatic hydrocarbons and phenols) and dissolved
40 formation minerals (anions and cations including heavy metals). Phenol contaminants are relatively soluble
41 in water and their severe toxicity even in low concentration have been reported worldwide (Mahiuddin,
42 Fakhruddin and Al-Mahin, 2012). The removal of phenol from effluents has been quite challenging and
43 expensive. Of the different technologies being applied to remove phenolic compounds from polluted areas,
44 biodegradation process is relatively low cost, no chemicals used, and high public acceptance tends to
45 destroy the pollutants if possible or at least to transform them to less harmful forms (Mahiuddin et al 2012,
46 Poi, Aburto-Medina, Mok, Ball, & Shahsavari, 2017).

47

48 **Microbial immobilization**

49 Microbial immobilization occurs naturally around the world (Bayat, Hassanshahian, & Cappello, 2015). It
50 offers a lot of advantages over the free form of microorganisms in bioremediation, some of which are:
51 provision of high biomass, high metabolic rate, improving genetic stability, resistance to toxic chemicals,
52 elimination of cell washout problems etc. (Bayat et al., 2015; Cláudia et al., 2013; Liu, Guo, Liao, &
53 Wang, 2012)

54 **Materials and Methods**

55 **Bacteria source and consortium**

56 The bacterial consortium used in this study were isolated from crude oil polluted creeks of Bodo, in
57 Gokana local government area of Rivers State. The water samples were enriched in 98ml Bushnell Haas
58 media (BHM), prepared according to manufacturer's specification and supplemented with 1% Bonny Light
59 crude oil (BLCO). One per cent crude polluted pond water samples were added to the sterile setup and
60 incubated in an orbital shaker incubator (Stuart, Germany S150) at 170 r.p.m at 37°C for seven days

61 (Ekwuabu, Chikere, & Akaranta, 2016; Xue et al., 2017). Further enrichments were conducted to obtain the
62 selected strains, which were sub-cultured separately in nutrient broth medium for 24 hours. After
63 incubation, the cells were harvested by centrifugation, washed with normal saline (0.85% NaCl) and re-
64 suspended in fresh normal saline. Equal volumes of the suspension containing the different bacterial strains
65 were mixed to form the consortium used in the study.

66
67 The selected strains were identified as 100% *Pseudomonas aeruginosa* (MN294989), 99% *Bacillus*
68 *tequilensis* (MN294990) and 63% *Micrococcus spp.* using the 16S rRNA approach.

69 **Screening for phenol and naphthalene degrading organism**

70
71 The method of screening adopted was similar to Velmurugan & Arunachalam, (2009). One ml of water
72 sample (one gram for soil sample) was serially diluted up to 10^{-6} dilution and spread on Bushnell Haas agar
73 medium containing 10 mg/ 100 ml phenol and naphthalene which was added after sterilization, and the
74 plates were kept for incubation at 28°C for 5 days.

75 76 **Enrichment of the isolated phenol and naphthalene degrading strains**

77 The 24 hours selected cultures were prepared in nutrient broth. One ml of this turbid broth was taken and
78 added into 99 ml of liquid mineral medium supplemented with 10 mg of phenol and naphthalene in a sterile
79 250 ml conical flask and kept in a rotary shaker at 120 rpm for 5 days.

80 81 **Selection of potential phenol and naphthalene degrading strains (Plate method)**

82 Minimal agar medium was prepared with increasing concentration of selected phenol and naphthalene as
83 follows 10 mg/100 ml, 20 mg/100 ml, 30 mg/100 ml, 40 mg/100 ml, 50 mg/100 ml and 100 mg/100 ml of
84 enriched cultures were inoculated on minimal agar media. Plates were incubated at room temperature for
85 48-72 hrs.

86 **Biocarriers**

87 Raw materials used as bio carriers (sugarcane bagasse, groundnut shell and melon husk) were all obtained
88 from Nchia Market in Eleme local government area of Rivers State. These agro-based residues were first
89 air-dried, grind mechanically and sieved to obtain a homogenous particle size of 0.3-0.5mm. They were
90 washed sequentially with ethanol and distilled water several times to prevent the impurities from affecting
91 the growth and immobilization of the bacteria. The powder was dispensed in vials and sterilized by
92 autoclaving at 120°C, 1 atm for 15 min and kept at room temperature until use.

93 **Surface area and pore distribution of carriers**

94 The surface area and pore size distribution of the carriers were analyzed based on the Brunauer-Emmett-
95 Teller (BET) theory. This is based on the adsorption of gas molecules on solid surfaces. Before analysis,
96 the samples were left in a desiccator at low temperature to ensure that they have as little remaining water
97 vapour as possible. The analysis was performed by the BET analysis instrument, according to the
98 manufacturer's specifications. The out-gassed samples are immersed in a liquid nitrogen bath while the
99 instrument performs the nitrogen adsorption tests.

100 **Scanning electron microscopy**

101 The scanning electron microscopy (SEM) was performed to examine the physical structure of the samples
102 as well as the adsorption of the microbial cells on them. This was done using SEM model Phenom ProX,
103 by Phenom-World Eindhoven, The Netherlands. Sample which was sputter-coated by quorum technologies
104 model Q150R 5nm of gold was placed on double-adhesive which was on a sample stub. Thereafter it was
105 taken to the chamber of SEM machine where it was viewed via NaVCaM for focusing and little
106 adjustment. This was then transferred to SEM mode where focusing was automatically adjusted. The
107 morphologies of different magnification were recorded.

108

109 **Immobilization of bacterial consortium**

110 About 0.5 g of the sterilized agro-based bio carriers were aseptically transferred into 500 mL of Bushnell
111 Hass broth in separate one litre Erlenmeyer flasks. Five millilitres of the bacterial consortium was
112 inoculated into the separate flasks containing the different carriers. After three days of incubation, the
113 powder was harvested, washed by sterile 75% normal saline, and air-dried.

114

115 To determine the population of the bacteria consortium that immobilized on the bio carriers. They were
116 washed with saline solution by centrifugation at 4000 rpm for 10 minutes to remove microorganisms that
117 were not immobilized on the carriers. The microorganisms immobilized on the bio carriers were harvested

118 by centrifugation at 8000 rpm for 10 min. The number of bacteria was approximately 5×10^7 CFU/ml in
119 the experiment and was determined using the dilution plate method.

120

121 **Wastewater sample collection**

122 The wastewater samples were collected from the raw wastewater and treated wastewater reservoirs in Port
123 Harcourt Refinery Eleme, Nigeria, and transferred to the laboratory immediately for analysis. All the
124 collected samples were preserved and processed following standard guidelines. The samples were analysed
125 for pH, Biological Oxygen Demand (BOD₅), Chemical Oxygen Demand (COD), total dissolved solids, oil
126 and grease, phenol, sulphide and some selected heavy metals.

127

128 **Bioremediation using immobilized mixed culture**

129 The efficacy of the immobilized consortium in bioremediation of refinery wastewater was determined in
130 microcosm trials. Batch cultures were performed using one-litre conical flasks containing 500ml refinery
131 wastewater autoclaved at 121°C for 15 minutes at 15 psi. On cooling, 0.5g of the immobilized consortium
132 is introduced separately in each of the conical flasks. The control had the sterilized raw wastewater only.
133 The different treatment options and the content of each representative flask are shown in table 1. The
134 samples were analyzed for pH, Biological Oxygen Demand (BOD₅), Chemical Oxygen Demand (COD),
135 total dissolved solids, oil and grease, phenol, sulphide and some selected heavy metals on every five days
136 intervals

168 **DISCUSSION**

169 This work aims at mitigating the challenges of maintaining high bacterial biomass on contaminated sites by
170 bacterial immobilization on organic bio carriers. Figures 1 to 3 shows the scanning electron micrographs of
171 the adsorbed consortium on the agro-based bio carriers. Surfaces properties affect bacterial adsorption on
172 them. Organic bio carriers have many functional groups and this affects the degree of colonization by
173 microorganisms (Dzionic, Wojcieszńska, & Guzik, 2016). The micrographs show the strong attachment
174 of the consortium on the pores and surfaces of the agro-wastes. Cell immobilization through adsorption
175 brings about direct contact between nutrients and immobilized cells (Lin, Liu, Chen, Wang, & Hu, 2014).
176 Udawatte & Sotheeswaran, (2015) suggested that nutrient absorbed from carrier substrates could be an
177 advantage to efficient colonization.

178 The results for the screening of potential phenol degrading strains as shown in table 3 indicated the ability
179 of the isolates to thrive in concentrations of 50mg/100ml. All the isolates produced visible colonies after
180 five days of incubation at 170 r.p.m at 37°C. At a concentration of 100mg/ml, only the *Bacillus tequilensis*
181 produced three visible colonies after 72 hours of incubation.

182 Results of the 15 days laboratory-scale treatment of refinery raw wastewater is presented in table 4. The
183 initial concentration of phenol in both the raw wastewater and the refinery treated wastewater were higher
184 than the DPR effluent discharge standard. After the treatment period, 99.7% removal of phenol was
185 recorded in GS-treatment option while the least removal was in the FB-treatment. However, only the GS-
186 treatment reduced phenol concentration below the DPR limit.

187 Phenol degradation by microorganisms can involve the use of enzymes such as hydroxylase,
188 monooxygenase and dioxygenase (Rehman and Ilyas, 2008). Aerobically, phenol is first converted
189 (through oxygenation) to catechol and subsequently degraded via the ortho or meta fission to
190 intermediates of central metabolism. This ring fission process is catalyzed by either an ortho cleaving

191 enzyme, catechol 1, 2- dioxygenase or by a meta cleaving 2, 3- dioxygenase enzyme (Sridevi, Lakshmi,
192 Manasa, & Sravani, 2012) Compared to physical and chemical methods, biological treatment is preferable
193 as it is relatively cheaper and reduces the challenges of by-products production.

194 Phenol removal in refinery effluents has been a very challenging process in wastewater treatment. The
195 chemical treatment with hydrogen peroxide before loading in the rotary bio-disc is a very expensive
196 procedure. The result shows that the selected consortium was able to degrade the phenol in the wastewater.
197 The bacteria employed as a consortium in this study have previously been associated with hydrocarbon
198 degradation. *Pseudomonas aeruginosa* and *Bacillus* sp. had been used as a consortium in phenol
199 degradation (Poi et al., 2017; Velmurugan & Arunachalam, 2009) while *Micrococcus luteus* had previously
200 been mentioned as hydrocarbon degraders (Obuekwe & Al-Muttawa, 2001; Rehman and Ilyas 2008).

201 Results of the physicochemical parameters of the Port Harcourt refinery raw wastewater effluents before
202 and after treatment with the agro-waste immobilized bacterial consortium are presented in table 4. The
203 major source of concern in an effluent discharge into the environment includes the presence of polycyclic
204 and aromatic hydrocarbons especially phenol, metal derivatives, high COD and BOD₅.

205 BOD₅ and COD values are often used as an indicator of water quality and their removal efficiencies are
206 used to comparatively analyze a variety of wastewater treatment systems (Baharvand, Reza, & Daneshvar,
207 2019). The efficiency of treatment plants can be assessed based on the chemical parameters of BOD and
208 COD (Carducci & Verani, 2013). The BOD₅ and COD values in the raw wastewater were 146.8±8.24 and
209 269.4±12.50. After a 15-day treatment with the different carrier-immobilized consortia, BOD₅ values of
210 4.6±0.49, 6.4±0.47, 14.5±0.21 and COD values of 24.5±0.21, 28.4±0.28 and 46.6±0.00 were obtained for
211 SB, GS and MH respectively while the immobilised consortium had values of 14.8±0.46 and 48.6±2.51 for
212 BOD₅ and COD respectively. The results indicated that the immobilized consortium was more effective in

213 the treatment process than the free form of the consortium, with SB and GS options showing higher
214 efficiencies in BOD₅ and COD removal.

215 When oil-containing hydrocarbons are discharged into a water body, they can cause depletion of
216 dissolved oxygen due to transformation of organic components into inorganic compounds (Ajao, Yakubu,
217 Umoh, & Ameh, 2013), and this has potentially damaging effects on aquatic organisms. Oil and grease
218 values were reduced by 94%, 87%, 74% and 64% in the SB, GS, MH and FB treatment options. Oil and
219 grease removal was highest in SB treatment option and least in the immobilised consortium.

220 Bacterial recovery during storage is shown in figure 4. After storage for 120 days, the highest cell recovery
221 was recorded in the GS-immobilized consortium and the least was in the MH-immobilized consortium.
222 Viable counts of up to 10⁴ for GS and SB, and 10³ for MH were recorded after 120 days from the initial
223 count of 10⁷. Nuñal et al., (2014) suggested that the obtained bacterial counts may be lower than the actual
224 counts as strongly adsorbed bacteria may be difficult to dislodge. Nuñal et al., (2014) had reported cell
225 viability after storage of rice hull and cocopeat-immobilized bacterial consortia at temperatures of -30C,
226 0°C, and room temperatures after six months. This result suggests that immobilized cells can be stored
227 without losing their metabolic activities.

228 **Conclusion**

229 This work underscores the potential of an agro-waste immobilized consortium of three hydrocarbon
230 utilizing bacteria isolated from the oil-polluted environment in Bodo creeks, of Gokana local government
231 area of Rivers state to effectively treat refinery raw wastewater. Bacteria immobilization on agro-waste
232 materials could be introduced into refinery wastewater treatment protocols as a means of enhancing the
233 treatment process. The agro-based residue immobilized consortium enhanced the reduction in BOD₅, COD,
234 oil and grease, phenol by 7%, 9%, 30% and 5% respectively compared to the free form of the consortium.

235 This study underscores the role of immobilization in maintaining high bacterial biomass on contaminated
236 site and possible improvement in bioremediation of refinery wastewater.
