

Light Emitting Diode (LED) Bulb Aspiration in Northern Ghana: A Case Report and Literature Review

ABSTRACT

Light emitting diode (LED) bulb is an unusual cause of foreign body aspiration. We present a case of a 6-year-old boy who reported with a four-day history of difficulty in breathing and cough following a LED bulb aspiration retrieved via rigid bronchoscopy. This present case suggests that LED bulb should be considered in the differential diagnosis of foreign body aspirations in our environment.

Keywords: LED, bulb, Aspiration, bronchoscopy, Northern, Ghana.

1. INTRODUCTION

Foreign body aspiration is a well-known life-threatening emergency in children especially below the age of three years [1]. Previous studies in Ghana reported groundnuts, corn, seeds, plastics and metallic objects as the most commonly aspirated foreign bodies [1–4]. Globally only six cases of LED bulb aspiration have been reported [5–10]. The gold standard for treatment of foreign body aspiration is rigid bronchoscopy. This article presents our first case of LED bulb aspiration in a six-year-old boy with literature review on LED bulb aspiration.

2. CASE REPORT

Our patient was a six-year-old boy who presented with four-day history of difficulty in breathing and dry cough. Prior to presentation patient was in school sleeping with a LED bulb in

his mouth when a colleague suddenly startled him and he accidentally aspirated the LED bulb. He reported to our facility when the symptoms were not subsiding. There was no history of fever, dysphagia or odynophagia.

On examination, the oxygen saturation was 92% on room air with alar nasal flaring. Air entry was reduced on the right hemithorax with vesicular breath sounds. Chest X-ray showed a metallic wire-like shadow in the right main bronchus (Fig. 1). An initial diagnosis of foreign body aspiration was made. Patient was given 2L/minute of intranasal oxygen and subsequently prepared for emergency rigid bronchoscopy. A LED bulb was retrieved from the right main bronchus (Fig. 2). There was no perioperative complication. Patient was discharged home on the third postoperative day and eight months follow up was unremarkable.

3. DISCUSSION

Foreign body aspiration is a pediatric emergency which needs to be managed with initial resuscitation and early removal of foreign body

via a bronchoscope [2], [5–7]. Many patients succumb to death before reaching any health facility equipped to perform rigid bronchoscopy.

There have been numerous reports of foreign body aspiration in literature, including one of our previous study revealing groundnuts to be the most commonly aspirated material and children younger than 3 years are most vulnerable in more than 70% of cases [2], [8].

In the event of suspected foreign body aspiration, bronchoscopy should be done without delay due to the fact that accurate clinical diagnosis of foreign body aspiration is usually around 60% [5], [6].

This is our first case of LED bulb aspiration into the right main bronchus which we successfully retrieved by rigid bronchoscopy using advanced bronchoscope and imaging systems. LED bulb is a rare cause for tracheobronchial aspiration and only six cases have been reported in the literature so far with a total of 8 cases [5–10]. We reviewed the six published literature reports. The first case of LED bulb aspiration was reported in the 21st century by Mukherjee et al [5]. They reported 2 cases of LED bulb aspiration out of 74 cases of foreign body aspirations. The latest reported cases of LED bulb aspiration was in 2017 from France and India (Carsin, Baravalle-Einaudi, & Dubus, 2017; Sikdar et al., 2017).

In recent years, usage of LED bulbs has gained popularity in the toy, lightening and entertainment industry, which accounts for the recent increase in reports of its aspiration. It is possible the number of LED bulb aspiration cases are higher than reported as many authors only report on the common foreign bodies aspirated and tend to summarize the less frequent ones and thereby omitting the incidence of LED bulb aspiration.

4. CONCLUSION

In conclusion, LED bulb should be considered in the differential diagnosis of aspirated foreign bodies in Ghanaian children. We add our voice to the call of creating awareness of LED bulb aspiration in caretakers and health workers in the prevention, diagnosis and timely intervention in a center with expertise in rigid bronchoscopy.
