

1 **Genetic manipulation and product shelf life: Is there a connection?**

2 **A developing world perspective**

3

4 **ABSTRACT**

5 Genetic manipulation of plants is the science where there is deliberate
6 modification of the genetic make up of plants. Such plants are referred
7 to as genetically modified (GM) organisms. The practice of genetic
8 manipulation of organisms has been practiced since ancient times, its
9 only that nowadays there is use of advanced technologies. However
10 there are critics of GM technologies which include organic farmers,
11 religious groups, environmentalists, trade protectionists, some
12 politicians, some naturalists and African traditionalists. Some of the
13 fears pertain to potential toxicity, allergenicity, possible antibiotic
14 resistance, carcinogenicity and possible genetic contamination of other
15 crops and wild flora. Other concerns include possible creation of new
16 viruses, restriction of seed availability and fear of the unknown. On the
17 other hand there are benefits which may outweigh the disadvantages of

18 GM technology. Benefits include improvement of shelf life of fruits and
19 vegetables and their nutritional content. **The aim of this study (review)**
20 **was to explore the link between genetic manipulation and product shelf**
21 **life of fruits and vegetables in a developing world perspective.**

22
23 **Keywords:** Genetic engineering, plant breeding, risks, benefits, shelf
24 life, fruits and vegetables, African traditionalists, food security.

26 **1. Introduction**

27 Genetic engineering is described as the science and art whereby the
28 characteristics of an organism are deliberately modified by the
29 manipulation of the genetic material, especially DNA and transformation
30 of certain genes to create new variations of life [1,2,3] .

31 The recombinant DNA technique is whereby DNA is manipulated in
32 various ways and transferred from one organism to another. Transgenic
33 organisms are programmed to manufacture substances such as
34 monoclonal antibodies, hormones, nutrients, enzymes and various
35 pharmaceutical products like vaccines and drugs [4,5,1]. Cloning of

36 organisms which include plants, bacteria, fish and livestock has been
37 done. The potential for gene splicing techniques, gene editing and other
38 biotechnological procedures [2]. such as cloning have been compared in
39 popular press with the discovery of fire, invention of the printing press
40 and splitting of the atom [1].

41
42 Plant biotechnology involves the manipulation of biological systems to
43 solve problems in industry and agriculture, fundamental techniques that
44 affect various aspects of the regulation of gene expression [6]. Many
45 food plants have been genetically engineered for various purposes. Some
46 fruits and vegetables have been genetically manipulated to affect product
47 shelf life [7,3].

48

49 **2. Importance of Fruits and Vegetables**

50 Plants are an important source of energy in developing countries and
51 developed countries. Fruits and vegetables are important for their
52 nutritional contribution as major sources of vitamins and minerals and
53 for fibre provision and hence ensure a balanced diet [8,9]. Broccoli and

54 cauliflower are prime examples of vegetables that have gained
55 dramatically in popularity due to evidence from the American Cancer
56 Society that including them in a high-fiber, low-fat diet may reduce the
57 risk of cancer [9]. Fruits and vegetables are generally poor sources of
58 protein because of low content exceptions are legumes. Men and animals
59 are supplied by plants with nine essential amino acids which animals
60 cannot synthesize. The nine essential amino acids are histidine, leucine,
61 isoleucine, lysine, methionine, threonine, valine, tryptophan and
62 **phenylalanine** [10]. Fruits and vegetables are generally not high in fats
63 or oils, exceptions are oil seeds. Fats are an energy source and are
64 required for the formation of protective layers. The good thing about
65 vegetable oils is that they are unsaturated oils (containing at least a
66 double bond in the carbon chain) which are good for the body especially
67 the heart and cardio-vascular system.

68 Vitamins are the major contribution of fruits and vegetables to the
69 human diet. Vitamin A- from β -carotene provided for by orange
70 coloured fruits and vegetables, Vitamin A is important for proper eye
71 function. Vitamin K, B complex and vitamin C obtained from fruits and

72 vegetables are very important for proper body function [11]. Fruits and
73 vegetables are major sources of minerals eg. calcium and phosphorus-
74 many fruits and vegetables are good sources while leafy vegetables are
75 good sources of iron. In fact fruits and vegetables play an aesthetic role,
76 providing interesting colour, texture and variety in food.

77 **3. History of Genetic Manipulation of Fruits and Vegetables**

78
79 Genetic manipulation of plants by man in order to obtain desired or
80 eliminate undesired attributes has been practiced since pre-historic
81 times. Genetic engineering has been practiced by resourceful farmers
82 who bred plants and animals to obtain certain attributes, by gathering
83 and planting seeds of fatter grains and by cross- fertilizing different
84 species of plants to create new varieties that exhibit the most desirable
85 characteristics of the parent plants [12,1]. Traditional plant breeding
86 was largely by chance (imprecise), slow and it took a long time to
87 produce a valuable variety [2]. In 1967 a new potato variety called
88 Lenape potato was bred for its high solids content which made it more
89 suitable for making potato chips [1]. However it was withdrawn by the

90 USDA after it was found to be prone to development of an alkaloid
91 (toxin) called solanine. In this case biotechnology proved that it can lead
92 to unexpected outcomes.

93 In the 1980s researchers in West Germany (Max Planck Institute for
94 Plant Breeding), Belgium and in the United States (Monsanto
95 Corporation) found a method of creating transgenic plants using a
96 pathogenic bacterium (*Agrobacterium tumefaciens*) [13,14,1]. Many
97 traits were introduced into other plants [15] including slow ripening of
98 tomatoes [1].

99

100 **4. Potential Risks of GM Fruits and Vegetables.**

101

102 There are some potential risks of GM foods including GM fruits and
103 vegetables. The critics of genetically manipulated foods have concerns,
104 not only for safety, toxicity, allergenicity, carcinogenicity and altered
105 nutritional quality of foods, but also for the environment (Table 1) as
106 Eswatini strives to achieve sustainable development goals (SDGS).

107

108

109 **Table 1.** Potential risks or concerns from use of GM foods.

110 Risks or Concerns

111 Alteration in nutritional quality of foods

112 Antibiotic resistance

113 Potential toxicity from GM foods

114 Potential allergenicity from GM foods

115 Unintentional gene transfer to wild plants

116 Possible creation of new viruses and toxins

117 Limited access to seeds through patenting of GM food plants

118 Threat to crop genetic diversity

119 Religious/cultural/ethical concerns

120 Concerns of animal rights groups

121 Concerns of organic and traditional farmers

122 Fear of the unknown

123 Source: [1]

124

125 **5. Benefits of GM Fruits and Vegetables.**

126 There are several benefits of GM foods including GM fruits and
127 vegetables. Supporters of the genetic manipulation of foods cite
128 increased year-round availability, extended shelf life and improved
129 nutritional quality as some of the reasons (Table 2) why they encourage
130 the new science which will benefit farmers, consumers and the
131 environment [1].

132

133 **Table 2.** Potential benefits from GM technology.

134 Benefits of GM technology

135 Increase in food availability

136 Improved shelf life and organoleptic quality of foods

137 Improvement in nutritional quality and healthy benefits

138 Improved protein quality

139 Increase in food carbohydrate content

140 Improvement in quantity and quality of meat, milk and livestock

141 Increased crop yield.

142 Manufacture of edible vaccines and drugs
143 Biological defense against diseases, stresses, pests, weeds, herbicides
144 and viruses.
145 Bioremediation
146 Positive effect on farming/food product
147 Protection of the environment
148 GM crops function as bio-factories and source of industrial raw
149 materials

150 Source: [1]

151 **6. Extended fruit and vegetable shelf life and organoleptic quality**

152
153 The GM technology has led to extended shelf life and organoleptic
154 quality of some commodities including fruits and vegetables.

155 Calgene Corporation of California produced the first genetically
156 engineering tomato crop which was approved by the FDA [16, 17,
157 1]. **Flavar Savar** tomato had its genes manipulated so that it can
158 ripen on the vine and have a relatively longer shelf life with
159 delayed softening and rotting processes. Ethylene (C_2H_4) control

160 technologies may be used like suppression of gene expression of
161 ethylene synthesis or inhibition of ethylene perception. The
162 inhibitor of ethylene perception, 1 methylcyclopropene (1-MCP) is
163 the basis of a new technology that is increasingly being used to
164 improve storage potential and maintain quality of fruit and
165 vegetables. It is registered for use on a number of crops including
166 apricot, apple, banana, avocado, kiwi fruit, broccoli, mango, pear,
167 peach, melon, persimmon, nectarine, tomato and plums [18,19].
168 Genetic suppression of cell wall degrading enzymes may be used
169 i.e.pectin methylesterase (PME) and polygalacturonase (PG)
170 leading to longer shelf life, better handling and shipping properties
171 [20]. The slow or delayed ripening characteristics can be replicated
172 in other crops like strawberry, raspberry and pine-apple and can
173 extend the crops shelf life [1]. Good shipping and handling
174 properties will also benefit farmers and consumers in developing
175 countries like those in Southern Africa where refrigeration is
176 unreliable, expensive and transportation network is rudimentary
177 [21].

178 **7.Improved nutritional quality and health benefits.**

179 Genetic manipulation may help increase levels of minerals and naturally
180 occurring anti-oxidants (Table 3).

181

182

199

200

201 Vitamins (flavonoids, carotenoids, Vitamin A, C and E), compounds
202 that can shut down or slow biological oxidation, a damaging
203 chemical reaction, that appears to promote the development of
204 some cancers, blindness and heart diseases [23,24].

205 **8.GM Technology and Post-harvest crop protection**

206 After harvest fresh fruits and vegetables which are still alive face
207 challenges including disease infections and insect attack. Disease caused
208 by pathogenic fungi and bacteria infect fruits and vegetables in a
209 physiologically weakened state [25,26,27,28,29,30]. GM technologies
210 which interfere with C₂H₄ production, perception and action delays
211 senescence and thus keep harvested fruits and vegetables in a state not
212 prone to attack by opportunistic pathogens hence prolonged shelf life.
213 Healthy harvested fruits and vegetables are prone to attack by post-
214 harvest insect pest like the fruit fly and **weevils are attracted** to fruit by
215 the release of ripening stimulants which attract insects like fruit flies
216 [31,32,33]. The GM technologies reduce activities associated with cell
217 wall degrading enzymes which prevent harvested fruits and vegetables

218 from attack by opportunistic diseases and insect pests. The integrity of
219 cell walls of harvested commodities is maintained relatively for some
220 time. The cell wall degrading enzymes of importance include pectin
221 methyl esterase (PME) and polygalacturonase (PG) which act on pectin
222 and polygalacturonic acid polymer units, respectively. Keeping the cell
223 walls relatively inactive **by** suppression of gene expression of cell wall
224 degrading enzymes [16,7,3]. keeps the cell walls relatively intact and
225 subsequently act as the first line of defense of the harvested fruits and
226 vegetables against post-harvest opportunistic pathogens and insect pests.
227 In this way the use of post-harvest pesticides is avoided and this is not
228 only good for human health but also for the environment [34].

229

230

231 **9. Implications to food security**

232 Food security, as defined by the United Nations' Committee on World

233 Food Security, means that all people, at all times, have physical,

234 social, and economic access to sufficient, safe, and nutritious food

235 that meets their food preferences and dietary needs for an active

236 and healthy life [35]. There is need for adaptation strategies to

237 achieve nutritional and food security in countries of the

238 developing world including those of the Southern African

239 Development Community (SADC). Over the coming decades, a

240 changing climate, growing global population, rising food prices,
241 and environmental stressors will have significant yet uncertain
242 impacts on food security. Adaptation strategies and policy
243 responses to global change, including options for handling water
244 allocation, land use patterns, food trade, postharvest food
245 processing, and food prices and safety are urgently needed [36].
246 Food security/insecurity issues are crucial. For example food
247 insecurity is now recognized as a major health crisis in the United
248 States of America [37]. There is need to build momentum in
249 SADC for a future launching of a regional multi-stakeholder
250 hunger-free initiative for Southern Africa that builds upon existing
251 policies and programmes and amplifies the current political
252 commitment [36].

253 By manipulating C_2H_4 control technologies and suppression of cell
254 degrading enzymes PME and PG the shelf life of fruits and vegetables
255 can be extended. When the shelf life of fruits and vegetables is extended
256 it means their availability in the post-harvest handling chain is improved
257 up to market and consumption and thus subsequent improved food

258 security. With improved food security SADCs efforts of attaining SDGs
259 are accelerated.

260

261 **7. CONCLUSION**

262 It appears that there are overallly more benefits of use of GM
263 technologies than perceived adverse effects in fruits and vegetables
264 pertaining to extended shelf life. The use of C₂H₄ control
265 technologies and suppression of gene expression of cell wall
266 degrading enzymes PME and PG has potential post-harvest
267 benefits environmentally, physiologically, pathologically and
268 entomologically. Extended shelf life is an added benefit in terms of
269 improving nutritional and food security towards achieving SDGs.
