

# Adaptation approaches for direct seeded rice to reduce greenhouse gas emission in the perspective of climate change

## ABSTRACT

A field experiment was conducted at research farm, Bihar Agricultural University, Sabour during 2017 and 2018 to gain insight crop phenology mediated greenhouse gas emission under different tillage and nitrogen management practices in direct seeded rice (DSR). The experiment was conducted in split plot design with two tillage viz. zero tillage (ZT) and conventional tillage (CT) as main plot and four nitrogen management practices viz. 100% nitrogen through neem coated urea ( $S_1$ ), SPAD based nitrogen management ( $S_2$ ), 75% through neem coated urea + 25% nitrogen through Vermicompost, ( $S_3$ ) and  $\frac{1}{4}$  nitrogen as basal and rest in equal three splits at 20, 40, 60 DAS ( $S_4$ ) as sub plot, in three replication. The highest yield ( $4.69 \text{ t ha}^{-1}$ ), net return ( $46440 \text{ Rs ha}^{-1}$ ) and B:C ratio (1.44) were recorded from zero tilled DSR. Further, highest yield ( $4.82 \text{ t ha}^{-1}$ ), net return ( $44880 \text{ Rs ha}^{-1}$ ) and B:C ratio (1.36) was obtained under split application of nitrogenous fertilizers among other subplot treatments. The range of methane ( $0.57\text{-}1.47 \text{ mg m}^{-2} \text{ hr}^{-1}$ ) carbon dioxide ( $0.32\text{-}0.61 \text{ mg m}^{-2} \text{ hr}^{-1}$ ) and nitrous oxide ( $19.58\text{-}38.79 \mu\text{g m}^{-2} \text{ hr}^{-1}$ ) emission was recorded lowest in zero tilled plots and split application of nitrogenous fertilizer also emitted lowest values of  $1.59 \text{ mg m}^{-2} \text{ hr}^{-1}$  methane,  $0.86 \text{ mg m}^{-2} \text{ hr}^{-1}$  carbon dioxide and  $46.76 \mu\text{g m}^{-2} \text{ hr}^{-1}$  nitrous oxide at maximum tillering stage of crop growth. Moreover, methane and nitrous oxide emission was gradually decreased from maximum tillering to harvesting stage. Zero tilled DSR with split nitrogen fertilizer application ascribed lowest greenhouse gas intensity among the other crop establishment and nitrogen management options. Thus, zero tilled method of crop establishment with split application of nitrogenous fertilizer could be a remunerative and environmentally stable method for direct seeded rice cultivation.

**Keyword:** Direct seeded rice, Greenhouse gas intensity Nitrogen management, Zero tillage.

## 1. Introduction

Traditional rice establishment technique i.e. massive puddling followed by transplanting is not only exhaustive water user but also burdensome, energy consuming, and laborious process [1].

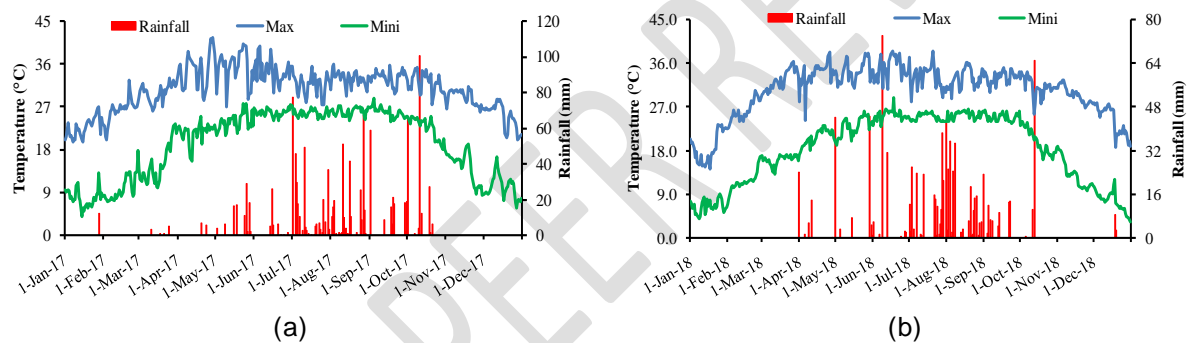

29 Conventionally, rice is established by repeated wet tillage (Puddling) followed by transplanting of the  
30 seedlings in the puddled soil while wheat established (in rice residue burned fields) by  
31 broadcasting/drilling seed after disking, tilling and planking operations [2]. Seed bed preparation  
32 operations oxidises the hidden organic matter, break the macro-aggregates into the micro-aggregates  
33 which adversely affect the soil properties [3,4]. Besides, soil perturbation by conventional tillage makes  
34 the soil to serve as a source rather than a sink of atmospheric pollutants [5]. About 20-40% of entire water  
35 required for growing crops is utilized in preparation of land for transplanting paddy. The situation could be  
36 further aggravated with degradation of soil fertility, declining underground water level and lesser per  
37 capita land availability and water productivity which ultimately are threat in front of sustainable rice  
38 production system. In addition, contribution of agriculture in total N<sub>2</sub>O, CH<sub>4</sub> and CO<sub>2</sub> emission are 60%,  
39 39%, and 1% respectively with rice based cropping system playing a principle role in global warming.  
40 Global CH<sub>4</sub> emission from rice paddies was estimated to be 20–40 Tg yr<sup>-1</sup> which accounted for  
41 approximately 5–19% of annual CH<sub>4</sub> emission to the atmosphere [6]. Nitrous oxide (N<sub>2</sub>O) emission from  
42 cultivated area of low land rice was much lower ranging from 1.7–4.8 Tg N<sub>2</sub>O N yr<sup>-1</sup> (Yao *et al.*, 2013).  
43 Therefore, direct seeded rice (DSR) is the only probable alternative by offering certain advantages like  
44 saving irrigation water, labour, energy time [7] for better growth of succeeding crops as well as by  
45 reducing emission of greenhouse gases [8] and fruitless water flows. Zero tillage or reduce tillage  
46 establishment which is extensively used for many crops around the world and this technology when used  
47 in rice cultivation has potential to allow saving in time, energy, water and labour during rice establishment.  
48 Moreover, Zero tilled or no tilled system of crop establishment not only reduce soil disturbance but also  
49 increases soil organic matter accumulation and can also increase crop yield [9, 10, 11]. Consequently,  
50 application of appropriate quantity of N at the right time to restrict rapid mineralization losses through  
51 different pathways before it is utilized by the crop is, therefore, one of the most important factors to realize  
52 high yield and N use efficiency in DSR. Thus, there is an urgent need to focus on input management  
53 practices for improving use efficiency and sustaining the rice based production system under lower  
54 emission scenarios. To address the issues of sustainability of food production on account of changing  
55 climate, a combination of tillage and nutrient management practices were tested aimed at (1) to gain  
56 insight crop phenology mediated greenhouse gas emission under different crop establishment and

57 nitrogen management practices and (2) to evaluate the effect of GHGs on productivity, profitability and  
58 subsequent impact on global warming.

## 59 2. MATERIALS AND METHODS

### 60 2.1 Experimental details

61 The field study was carried out at experimental farm of at Bihar Agricultural College Farm, Sabour during  
62 kharif season of 2017 and 2018. The climate of Sabour, Bhagalpur is sub-tropical having moderate  
63 annual rainfall, hot and dry summer and cold winter. Maximum and minimum temperature recorded for  
64 the same period varied in between 30.7 to 34.9 °C and 20.0 to 26.8 °C, respectively. Wind speed was  
65 varied from 1.2 to 5.0 km hr<sup>-1</sup>. The average annual rainfall of this place is about 1150 mm. Monthly  
66 average values of weather Parameters of 2017 and 2018 were presented in fig. 1(a) and (b).

67 Figure 1: Monthly mean weather parameter of 2017 and 2018

68 The initial status of soil was clay-loam with pH- 7.4, Electrical Conductivity- 0.29 dSm<sup>-1</sup>,  
69 organic carbon- 4.6 g kg<sup>-1</sup>, Available N – 228.5 Kg N ha<sup>-1</sup>, Available P- 19.22 Kg P<sub>2</sub>O<sub>5</sub> ha<sup>-1</sup>,  
70 Available K- 210.4 Kg K<sub>2</sub>O ha<sup>-1</sup>. The experiment was laid out in split plot design with 8 treatment  
71 combination and replicated thrice having two crop establishment method i.e. zero tilled DSR (M<sub>1</sub>), and  
72 conventional DSR (M<sub>2</sub>) and with four nitrogen Management Practices viz. S<sub>1</sub> as 100% nitrogen  
73 through neem coated urea where half was applied as basal and rest in two equal splits at active  
74 tillering and panicle initiation stage, S<sub>2</sub> SPAD based nitrogen management where SPAD threshold  
75 was 36 for rice whenever the SPAD reading was below critical value the N Fertilizer was applied (20  
76 kg ha<sup>-1</sup>) in form of Urea, S<sub>3</sub> with 75% through urea +25% nitrogen through vermicompost applied 15  
77 days before sowing. And S<sub>4</sub> in which ¼ Nitrogen as basal and rest 3 in equal splits at 20, 40, 60 DAS.  
78 , Each plot having dimension of 4.0X5.0 m<sup>2</sup> The plots were given uniform recommended dose of

79 phosphorus and potassium @ of 60 and 40 kg P<sub>2</sub>O<sub>5</sub> and K<sub>2</sub>O ha<sup>-1</sup> respectively, during the crop  
80 season.

81 Rice variety Rajendra Sweta was sown in mid June with seed rate of 50 kg ha<sup>-1</sup> at a row spacing of  
82 20 cm. The recommended dose of fertilizer of rice was 120 kg N + 60kg P<sub>2</sub>O<sub>5</sub> + 40 Kg K<sub>2</sub>O ha<sup>-1</sup> in  
83 which full P and K was applied in form of diammonium phosphate (DAP) and muriate of Potash  
84 (MOP) respectively as basal and nitrogen (Urea and DAP) was applied as per the treatment. Source  
85 of organic fertilization was Vermicompost with 1.5%N. Rice crop was harvested and threshed  
86 manually. Yield of rice was estimated by harvesting the entire plot and converted it to t ha<sup>-1</sup>. The grain  
87 yield of rice was recorded at 14% moisture.

## 88 2.2 Greenhouse gas (GHG) collection and analysis

89 The greenhouse gases i.e. CH<sub>4</sub>, N<sub>2</sub>O and CO<sub>2</sub> were collected from each plot through closed chamber  
90 method with the help of 50 mL disposable injection syringe with three way leur lock. At each sampling  
91 date, GHG samples were collected at 0, 30 and 60 minutes interval from each plot. The Gas samples  
92 were analyzed by a gas chromatograph (Trace GC 1100, Thermo Fischer) equipped with electron  
93 capture detector (ECD) and flame ionization detector (FID) for analysing N<sub>2</sub>O and CH<sub>4</sub> respectively.  
94 CO<sub>2</sub> was reduced to CH<sub>4</sub> with hydrogen in a nickel catalytic methanizer at 350°C and then detected  
95 by the FID. The carrier gas was nitrogen at a flow rate of 35 mL min<sup>-1</sup>. The temperatures for the  
96 column and ECD detector were maintained at 60°C and 300°C, respectively. The oven and FID were  
97 operated at 60°C and 300°C, respectively. The gas emission flux was calculated from the difference  
98 in gas concentration according to the equation of Zheng [12]

$$99 \quad F = \rho h \left( \frac{dC}{dt} \right) 273(273 + T)^{-1}$$

100  
101 where F is the gas emission flux (mg m<sup>-2</sup> hr<sup>-1</sup>), ρ is the gas density at the standard state, h is the height of  
102 chamber above the soil (m), C is the gas mixing ratio concentration (mg m<sup>-3</sup>), t is the time intervals of  
103 each time (h), and T is the mean air temperature inside the chamber during sampling.

## 104 2.3 Statistical analysis

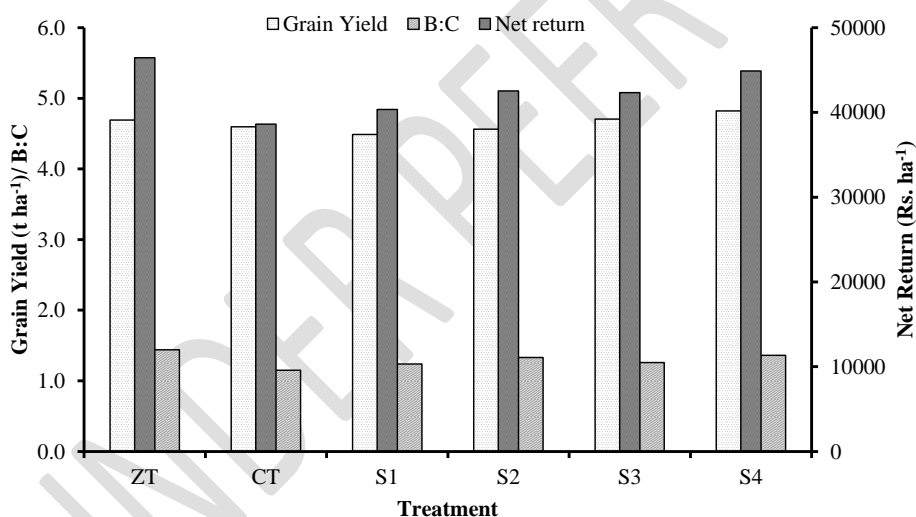

105 Analysis of variance (ANOVA) was done to determine treatment effects [13]. Duncan's multiple range test  
106 (DMRT) was used as a post hoc mean separation test ( $P=0.05$ ) using SAS 9.2 (SAS Institute, Cary, NC)  
107 [14]. The DMRT procedure was used where the ANOVA was significant.

### 108 **3. RESULTS AND DISCUSSION**

#### 109 **3.1 Grain yield and economics**

110 Different crop establishment and nitrogen management practices had significant impact on grain yield.  
111 Maximum grain yield ( $4.69 \text{ t ha}^{-1}$ ) was obtained from plots sown under zero tilled condition. Rice sown  
112 under zero tilled condition experienced reduced soil disturbance, resulting in increase in soil organic  
113 matter accumulation in top soil [15] which enhanced tillering capacity, lodging tolerance, greater stress  
114 resistance and wide ecological adaptability of rice crop [16]. Further, in zero tilled DSR there was more  
115 root length density of the crop which produces greater xylem exudates and transport these towards shoot  
116 at faster rates and thus helps in maintenance of higher chlorophyll level and photosynthetic rates of  
117 leaves resulting in more yield. The same was also confirmed by Jat et al [17]. Besides, there was also low  
118 sterility percentage resulting in more number of filled grains per panicle [18]. Significantly higher grain  
119 yield ( $4.82 \text{ t ha}^{-1}$ ) was recorded under split application of nitrogenous fertilizer compared to other sub plot  
120 treatments which gives adequate nutrient quickly as compared to organic substitute to the crop [19]. This  
121 is because of the fact that split application promotes higher leaf area index and dry matter production as  
122 well as effective tillers per meter square with more portioning of nutrients from source to sink and also due  
123 to lower weed infestation and higher nutrient utilization by efficient nitrogen management. Similar results  
124 were reported by [20]. Moreover, due to the fact that less nitrogen before anthesis and more nitrogen  
125 application at or after anthesis increase the post anthesis dry matter accumulation and grain filling [21].  
126 The yield ascribing character was the maximum under the three split nitrogen treatment resulting higher  
127 grain yield [21]. This may be attributed to the adequate N availability, at required crop growth stage which  
128 facilitates tillering, and develops more and heavier grains in rice crop. Additionally, cell elongation, cell  
129 enlargement and cell division due to proper utilization of nitrogenous fertilizer application under split  
130 nitrogenous fertilizer application, activates meristematic tissues which remain functional for longer periods  
131 resulting in better expression of yield and yield attributes and resulting in more yield of the crop. This  
132 result is in close agreement with those reported earlier [22, 23].

133 There was reduction in cost of cultivation in zero tilled DSR ( $M_1$ ) as compared to conventional DSR ( $M_2$ ),  
 134 probably due to the fact that in zero tilled plot less labours were required in addition with less cost in land  
 135 preparation due to no tillage operation which declined cost of cultivation [24] (Kumar et al. 2009).  
 136 Similarly, highest gross returns of  $78690 \text{ Rs. ha}^{-1}$ , net return ( $46440 \text{ Rs. ha}^{-1}$ ) and B: C ratio (1.44) was  
 137 recorded from treatment zero tilled DSR mainly because in Zero tilled DSR both of grain and straw yield  
 138 was high [25]. Among nitrogen management practices lowest cost of cultivation was incurred in SPAD  
 139 based nitrogen management ( $32125 \text{ Rs. ha}^{-1}$ ) compared to other treatments. It may be due to the fact that  
 140 in SPAD based nitrogen Management less amount of fertilizer was given to the soil. About 24% less  
 141 nitrogen was given in as compared to other nutrient management practices. The maximum gross return  
 142 of  $78005 \text{ Rs. ha}^{-1}$ , net return ( $44880 \text{ Rs. ha}^{-1}$ ) and benefit cost ratio of 1.36 was recorded from the crop  
 143 raised with three split application of nitrogen fertilizer. This is due to the fact that split fertilizer application  
 144 increases the nutrient use efficiency resulting in increased nutrient uptake which influences various  
 145 growth and yield attributing characters which attributes to higher gross return.

146

147 Figure 2: Effect of tillage and nitrogen management on Grain yield, net return and B:C ratio

148 **3.2 Greenhouse gas emission**

149 Rice cultivation is an important anthropogenic source of methane emission. The statistical analysis  
 150 revealed that lowest greenhouse gas emission was found in zero tilled plots irrespective of nitrogen  
 151 management practices (Table 1). However, significant variation was found in methane emission at  
 152 different stages of crop growth while there was no significant variation in nitrous oxide emission in

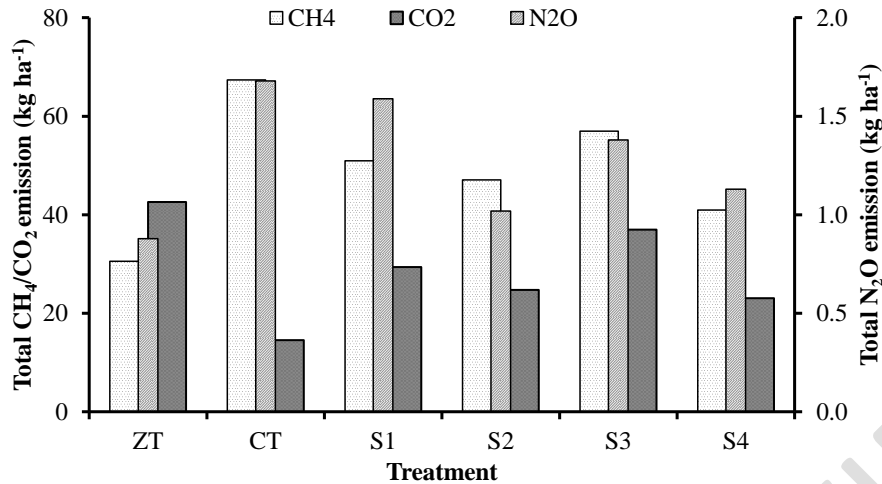

153 different crop growth stages. Lowest methane emission was under Zero tilled DSR (1.47,1.08 and 0.57  
 154 mg m<sup>-2</sup> hr<sup>-1</sup> at maximum tillering, panicle initiation and harvesting stage respectively) as compared to  
 155 Conventional tilled DSR. Although the emission followed decreasing trend from maximum tillering  
 156 stage of the crop to later on. Generally, methane emission from rice field mostly depends on input and  
 157 soil management practices. Anaerobic conditions are prerequisite for activities of methanogenic  
 158 bacteria that enhance methane production. Several studies proved that zero tilled DSR resulted in  
 159 lower methane emission than conventional DSR (Ahmed et al.2009) through preserving methane  
 160 oxidation potential that would get disturbed by tillage operation [26]. Basically, under zero tillage there  
 161 is no disturbance of soil cause less exposure of organic matter as caused by tillage operation [27].  
 162 Higher methane emission was recorded at maximum tillering stage is due to lower rhizospheric  
 163 methane oxidation and more effective transport mediated by rice plants [28], which was successively  
 164 decreased to panicle initiation and harvesting stage. The same trend of emission pattern was also  
 165 observed for CO<sub>2</sub> and N<sub>2</sub>O. Lower C<sub>2</sub>O emission of 0.61, 0.57, 0.32 mg m<sup>-2</sup> hr<sup>-1</sup> from maximum tillering,  
 166 panicle initiation and harvesting stage respectively under zero tilled condition. The emission of N<sub>2</sub>O

167 Table 1: Effect of tillage and nitrogen management on greenhouse gas emission

| Treatment      | CH <sub>4</sub> Emission (mg m <sup>-2</sup> hr <sup>-1</sup> ) |       |         | CO <sub>2</sub> Emission (mg m <sup>-2</sup> hr <sup>-1</sup> ) |       |         | N <sub>2</sub> O Emission (µg m <sup>-2</sup> hr <sup>-1</sup> ) |        |         |

169 ZT-Zero tillage, CT- Conventional Tillage, S<sub>1</sub>: 100% N through neem coated urea, S<sub>2</sub>: SPAD based N  
 170 management, S<sub>3</sub>: 75% N through urea + 25% N through organic, S<sub>4</sub>: ¼ of N as basal and rest in 3  
 171 equal split at 20,40 and 60 DAS  
 172  
 173

174

175

Figure 3: Total greenhouse gas emission from rice crop

176

ranged from 19.58 to 38.79  $\mu\text{g m}^{-2} \text{hr}^{-1}$  from zero till and from 46.54 to 63.46  $\mu\text{g m}^{-2} \text{hr}^{-1}$  from

177

conventional tillage. Plots with 100% nitrogen through neem coated urea emitted more nitrous oxide

178

that also lowers the methane and carbon dioxide emission, however, split of nitrogenous fertilizer

179

made lower emission irrespective of all three gases. Addition of organic matter to the soil increased

180

the decomposition rate of soil organic content which resulted in higher emission of methane [8].

181

Nitrous oxide emission from soil is mainly by microbial process of nitrification and denitrification also

182

[29]. Tillage may affect the biological, chemical and physical property of soil as well as influence the

183

greenhouse gas emission like nitrous oxide [30]. Although there is large uncertainty regarding higher

184

nitrous oxide emission under zero tilled DSR than conventional DSR [31] or nitrous oxide emission

185

diminishes after long term practices of zero tilled DSR. Under nitrogen management practices, split

186

doses of fertilizer application emitted lower ranged of all three greenhouse gases i.e. 1.59, 1.39, 1.08

187

$\text{mg m}^{-2} \text{hr}^{-1}$  for CH<sub>4</sub> and 0.86, 0.90, 0.66  $\text{mg m}^{-2} \text{hr}^{-1}$  for CO<sub>2</sub> and 46.76, 36.72, 28.02  $\mu\text{g m}^{-2} \text{hr}^{-1}$  for

188

N<sub>2</sub>O. It was also found that emission of nitrous oxide varied from 41.71 to 62.37  $\mu\text{g m}^{-2} \text{hr}^{-1}$  from 100%

189

nitrogen through neem coated urea i.e. maximum nitrous oxide emission was formed from this

190

treatment as under such conditions there are chances of rapid mineralization and prone to loss

191

through different pathways before it is utilized by crop. Fundamentally, application of nitrogenous

192

fertilizers as basal to the soil would have further increased the substrate availability for soil nitrous

193

oxide emission. Likewise, use of nitrogenous fertilizer is directly linked quantum of with nitrous oxide

194 (Smith and Conen 2004). Split application of nitrogenous fertilizer had lowest nitrous oxide emission at  
 195 each stage of crop growth, as application of adequate quantity of nitrogen at right time is one of the  
 196 most important factors for highest nitrogen use efficiency and lower loss as denitrification. Exclusion of  
 197 tillage (ZT) caused drastic reduction in total CH<sub>4</sub>, CO<sub>2</sub> and N<sub>2</sub>O emission, whereas split application of  
 198 N fertilizers also resulted lowest emission (Fig. 3). Relative contribution in global warming potential  
 199 (GWP) was highest in CH<sub>4</sub> (68-75%) followed by N<sub>2</sub>O (23-30%) and least in CO<sub>2</sub> (1-4%) (Fig. 4). GWP  
 200 was highest in CT-DSR (1931 kg CO<sub>2eq</sub> ha<sup>-1</sup>) which was double than ZT-DSR (949 kg CO<sub>2eq</sub> ha<sup>-1</sup>).  
 201 Among the nitrogen management strategies, splitting of N-fertilizer reduced the GWP by 22 and 26%  
 202 as compared to the 100% N through neem coated urea and 75% N through Urea + 25% N through  
 203 vermicompost, respectively.

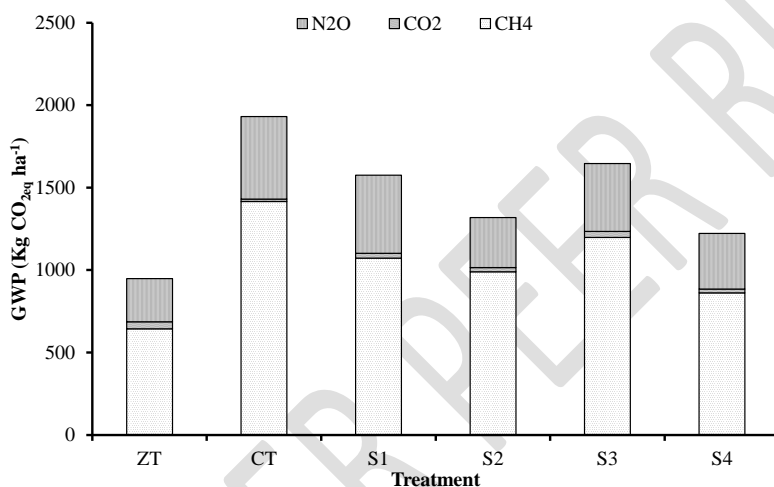

Figure 4: Relative contribution of GHGs in GWP

## CONCLUSIONS

Above study concluded that Zero tilled method of crop establishment along with split application of nitrogenous fertilizer would not only boost the yields but also decrease the greenhouse gas emission as well as global warming potential. Thus, the wider adoption of resource conservation approaches in direct seeded rice has long run benefits in terms of conserving natural resources, saving energy, higher production and cost effectiveness in the perspective of climate change.
